Example 9.8: Seepage through soil (p. 627)

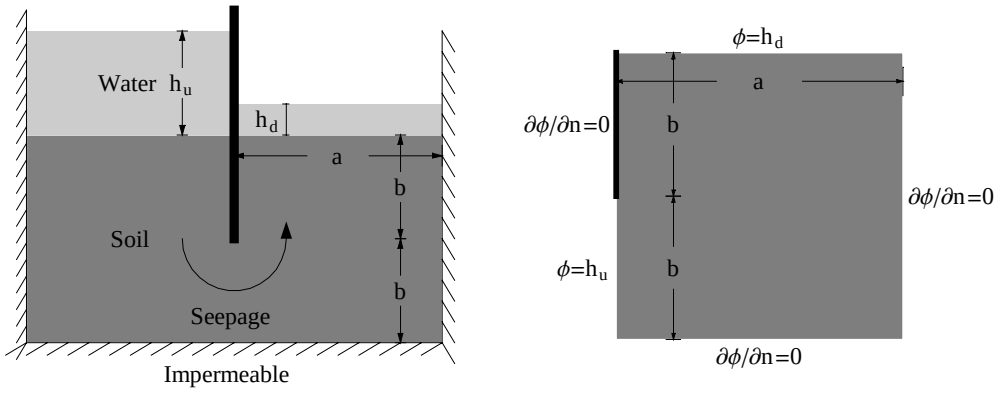
The problem of determining the amount of water that seeps through dams or from underneath sheet piles can be formulated in terms of the following equation

$$\frac{\partial}{\partial x}\left(k_x \frac{\partial \phi}{\partial x}\right) + \frac{\partial}{\partial y}\left(k_y \frac{\partial \phi}{\partial y}\right) = 0$$

where $\phi(x, y)$ is the hydraulic head (or hydraulic potential) and k_x and k_y are coefficients of permeability in the x and y directions. Typical units for ϕ are meters and those for k_x and k_y are m / day. The fluid velocity components in the x and y directions are related to the hydraulic head as follows.

$$v_x = -k_x \frac{\partial \phi}{\partial x} \text{ and } v_y = -k_y \frac{\partial \phi}{\partial y}$$

A typical situation is illustrated in Figure. The analytical model consists of the soil on the downstream side. On the impermeable sides the no flow condition is expressed in terms of normal derivative of ϕ being zero. On the top $\phi = h_d$ the hydraulic head on the downstream side. On the left side the boundary condition on the soil below the pile is $\phi = h_u$, the hydraulic head on the upstream side.



As a numerical example, consider the following numerical values.

$$a = b = 10\,m; \quad h_u = 10\,m; \quad h_d = 1\,m; \quad k_x = k_y = 1\,m/s$$

The solution domain is divided into four elements. Solution using second-order ($n = 2$) p formulation is as follows.

$$\partial\boldsymbol{N}^{\mathrm{T}}/\partial t = \left\{\frac{s-1}{4},\ \frac{1}{4}(-s-1),\ \frac{s+1}{4},\ \frac{1-s}{4},\ -\frac{\frac{3s^2}{2}-\frac{3}{2}}{2\sqrt{6}},\ \frac{1}{2}\sqrt{\frac{3}{2}}\,(s+1)\,t,\ \frac{\frac{3s^2}{2}-\frac{3}{2}}{2\sqrt{6}},\ \frac{1}{2}\sqrt{\frac{3}{2}}\,(1-s)\,t\right\}$$
